# CO<sub>2</sub> fertilization

- CO<sub>2</sub> increase in the atmosphere stimulates photosynthesis, and hence promotes net carbon uptake by land ecosystems.
- This effect forms a negative feedback loop: “CO<sub>2</sub>-carbon feedback”
- Another important feedback process: “climate-carbon feedback”

# Why CO2 fertilization effect ?

CO2 fertilization effect forms one of the strongest feedbacks in the Earth system, and has large uncertainty

Gregory et al. (2009) J. Clim

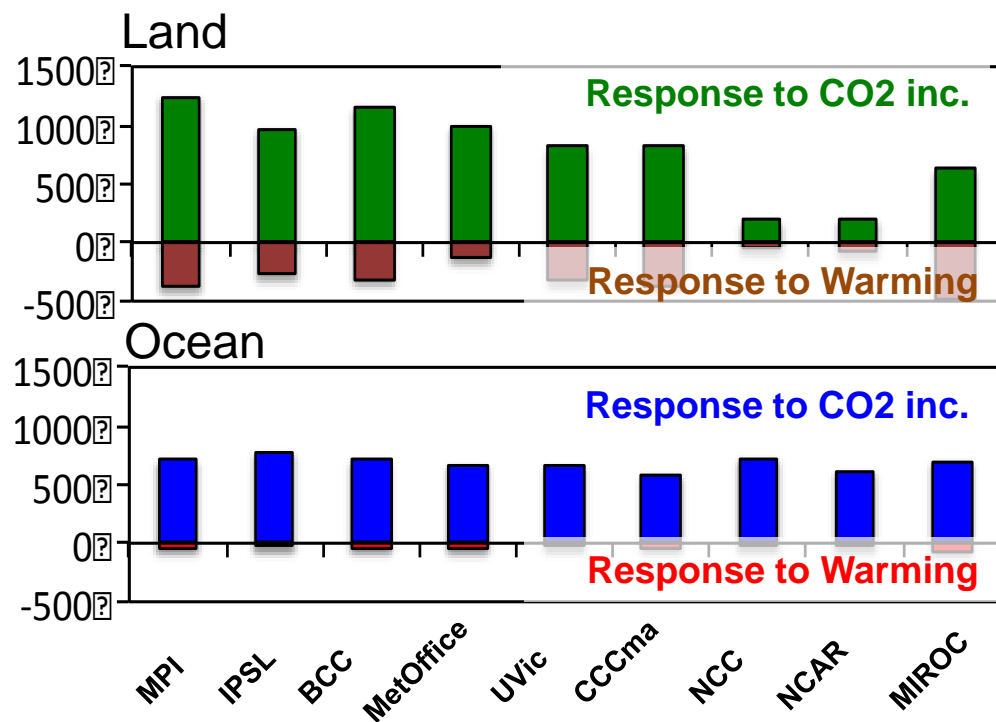

A comparison of components of feedback, based on CMIP3 AOGCMs and C4MIP (Friedlingstein et al. (2006)); grey bars indicate 1.65 S.D.;

# CO2 fertilization effect on terrestrial carbon change in ESMs

First investigation on CO2 fertilization effect using multiple climate-carbon cycle models was carried out by Friedlingstein et al. (2006) (but more attentions were paid to climate-carbon feedback).

In CMIP5, Arora et al. (2013) evaluated the two types of feedback by using total carbon change, and found large spread among models in the land response to CO2 increase.

These and other existing studies mainly analyzed the change in global terrestrial carbon storage, with limited focus on the mechanism of that.

# Purpose

- Identify the cause of large spread found in CMIP5-ESM on land carbon response to CO<sub>2</sub> increase, by evaluating the detailed process of land carbon cycle processes

# Method: decomposition of CO2 fertilization effect

$$\begin{array}{ccccccc}
 \frac{\Delta C_{LAND}}{\Delta CO_2} & = & \frac{\Delta gpp}{\Delta CO_2} & \times & \frac{\Delta GPP}{\Delta gpp} & \times & \frac{\Delta NPP}{\Delta GPP} & \times & \frac{\Delta C_{VEG}}{\Delta NPP} & \times & \frac{\Delta C_{SOIL}}{\Delta C_{VEG}} & \times & \frac{\Delta HR}{\Delta C_{SOIL}} & \times & \frac{\Delta C_{LAND}}{\Delta HR} \\
 \uparrow & & \uparrow & & \uparrow & & \uparrow & & \uparrow & & \uparrow & & \uparrow & & \uparrow \\
 \left( \begin{array}{c} \text{Land carbon} \\ \text{change by} \\ \text{CO}_2 \text{ increase} \end{array} \right) & & \left( \begin{array}{c} \text{Change in LAI} \\ \text{(gpp := GPP / LAI)} \end{array} \right) & & \left( \begin{array}{c} \text{Change in residence} \\ \text{time of veg. C} \end{array} \right) & & \left( \begin{array}{c} \text{Changes in} \\ \text{turnover rate} \\ \text{of soil C} \end{array} \right) & & \left( \begin{array}{c} \text{Change in} \\ \text{carbon} \\ \text{allocation} \\ \text{between veg-soil} \end{array} \right) & & \left( \begin{array}{c} \text{Change in} \\ \text{residence} \\ \text{time of eco. C} \end{array} \right) \\
 \uparrow & & \uparrow & & \uparrow & & \uparrow & & \uparrow & & \uparrow \\
 \left( \begin{array}{c} \text{Inc. in} \\ \text{photosynth} \\ \text{esis by CO}_2 \end{array} \right) & & \left( \begin{array}{c} \text{Change in} \\ \text{Carbon use} \\ \text{efficiency} \end{array} \right) & & \left( \begin{array}{c} \text{Change in} \\ \text{carbon} \\ \text{allocation} \\ \text{between veg-soil} \end{array} \right) & & \left( \begin{array}{c} \text{Change in} \\ \text{residence} \\ \text{time of eco. C} \end{array} \right)
 \end{array}$$

Similar to that used for “plant growth analysis” in ecophysiology:

$$\begin{array}{ccccccc}
 \frac{1}{M} \frac{dM}{dt} & = & \frac{1}{LAI} \frac{dM}{dt} & \times & \frac{LAI}{LM} & \times & \frac{LM}{M} \\
 \left( \begin{array}{c} \text{Relative} \\ \text{Growth Rate} \end{array} \right) & & \left( \begin{array}{c} \text{Net Assimilation} \\ \text{Rate} \end{array} \right) & & \left( \begin{array}{c} \text{Specific Leaf} \\ \text{Area} \end{array} \right) & & \left( \begin{array}{c} \text{Leaf Mass Ratio} \end{array} \right)
 \end{array}$$

*t: time; M: Dry matter; LAI: Leaf Area; LM: Leaf mass*

# Models & simulations

- CO2 increase by 1.0[%/yr] during 140 years
- Only carbon cycle “sees” the CO2 increase: named in CMIP5 as “esmFixClim1” (sometimes called “biogeochemically coupled” experiment)
- Eight CMIP5-ESMs

<u>Models</u>	
<u>ESM</u>	<u>Component for Land eco.</u>
BCC-CSM1.1	BCC-AVIM1.0
CanESM2	CTEM
CESM1-BGC	CLM4
HadGEM2-ES	TRIFFID
IPSL-CM5A-LR	ORCHIDEE
MIROC-ESM	SEIB-DGVM
MPI-ESM-LR	JSBACH
NorESM1-ME	CLM4

# Result: Decomposition

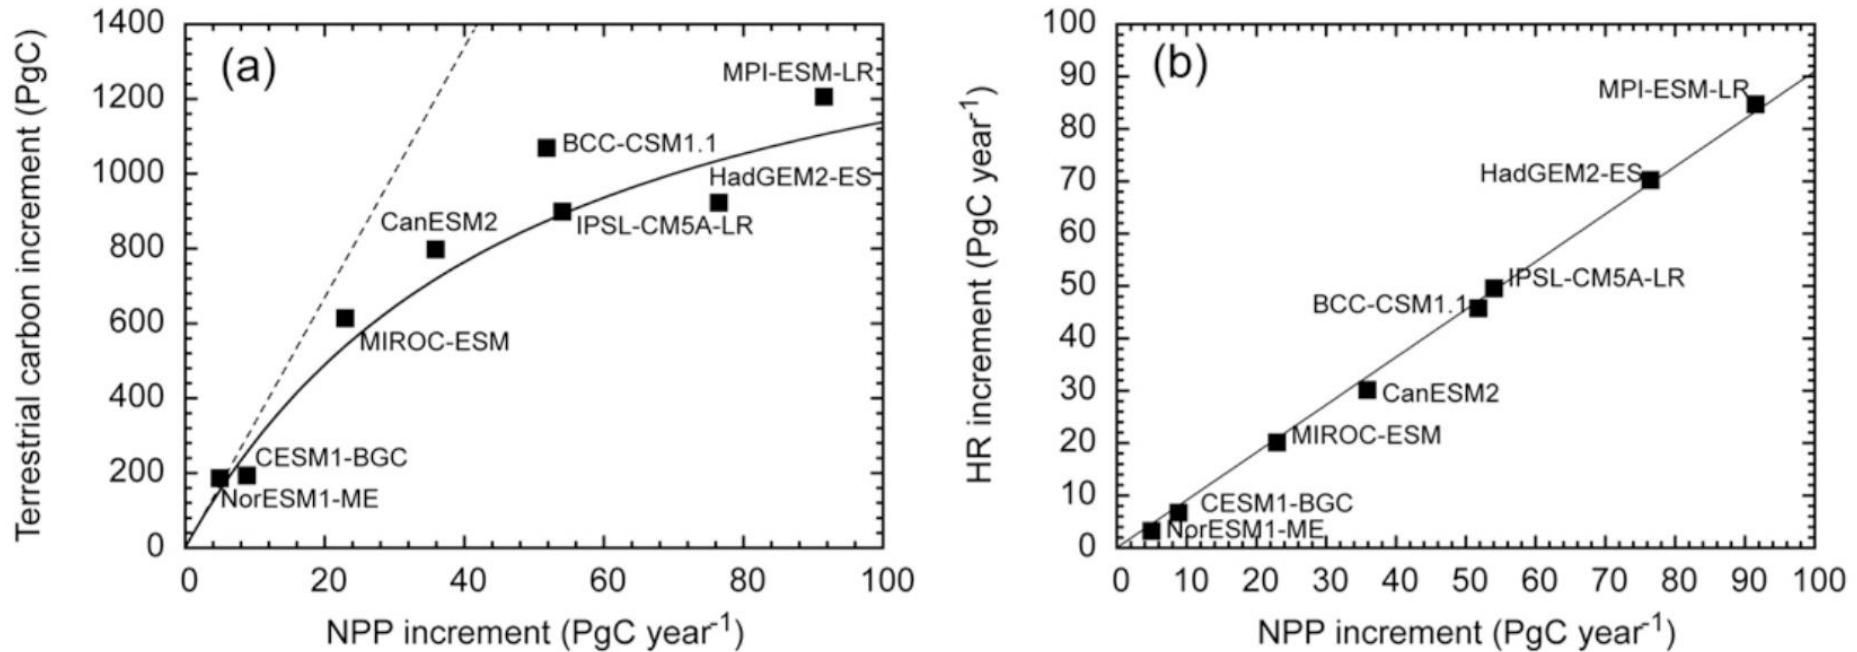

$$\frac{\Delta C_L}{\Delta \text{CO}_2} = \frac{\Delta gpp}{\Delta \text{CO}_2} \times \frac{\Delta GPP}{\Delta gpp} \times \frac{\Delta NPP}{\Delta GPP} \times \frac{\Delta C_V}{\Delta NPP} \times \frac{\Delta C_S}{\Delta C_V} \times \frac{\Delta HR}{\Delta C_S} \times \frac{\Delta C_L}{\Delta HR}$$

- CO2 increase does not only affect photosynthesis processes ( $\Delta gpp/\Delta \text{CO}_2$ ) but also stimulates the subsequent (“downstream”) carbon cycle processes.
- Models display different response pattern to the CO2 increase.
- This method can characterize the models’ response to  $\Delta \text{CO}_2$  in detail:  
e.g. Hadley & IPSL models show similar magnitude for  $\Delta C_L/\Delta \text{CO}_2$ , but IPSL model has stronger response in  $\Delta gpp/\Delta \text{CO}_2$  than Hadley and weaker in  $\Delta GPP/\Delta gpp$  (=ΔLAI)

# What controls CO<sub>2</sub> fertilization effect in CMIP5 ESMs?

- Although CO<sub>2</sub> increase stimulates various carbon cycle processes, total carbon change by CO<sub>2</sub> fertilization effect can be well explained by NPP increase in response to  $\Delta\text{CO}_2$ .
- Further evaluation of detailed processes (e.g.  $\Delta\text{gpp}/\Delta\text{CO}_2$ ,  $\Delta\text{GPP}/\Delta\text{gpp}$ ,  $\Delta\text{NPP}/\Delta\text{GPP}$  in the previous slide) and its constrain by observation would be needed to reduce the uncertainty.
- What are influential to global NPP: photosynthetic rate for individual leave, plant community LAI, and plant respiration rate; length of the growing season, and areas of plant and plant species distribution; nitrogen cycle

# Simplified model

The scenario dependence of the CO<sub>2</sub>-carbon feedback is investigated, using a simplified model.

$$\frac{dC_V}{dt} = \text{GPP} - (\text{AR} + \text{LF})$$

$$\text{GPP} = \text{GPP}_0 + \frac{k_{\text{GPP1}} \Delta \text{CO}_2}{k_{\text{GPP2}} + \Delta \text{CO}_2}$$

$$\text{AR} = k_{\text{AR}} C_V$$

$$\text{LF} = k_{\text{LF}} C_V$$

$$\frac{dC_S}{dt} = \text{LF} - \text{HR}$$

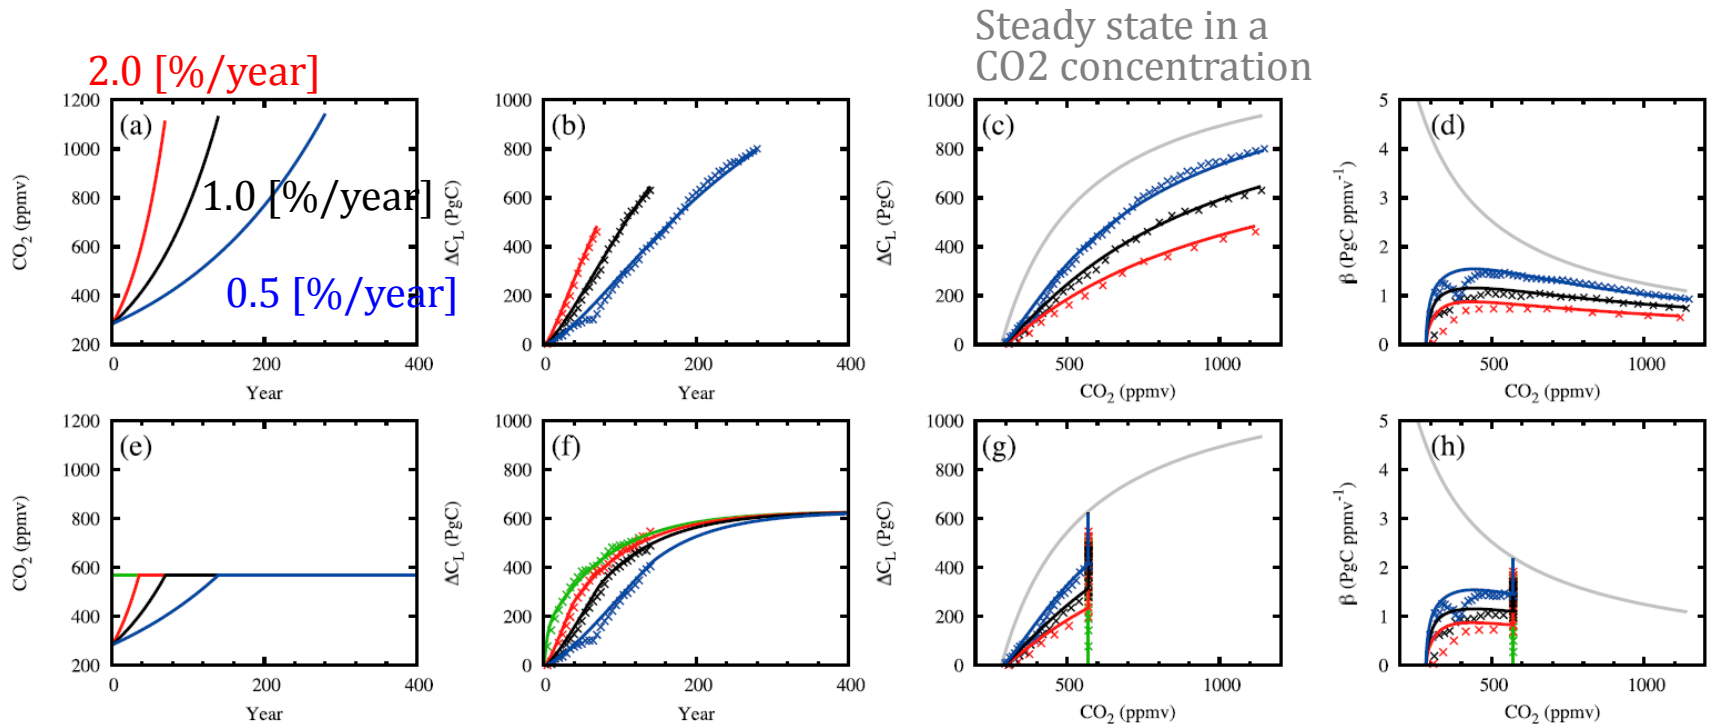

$$\text{HR} = k_{\text{HR}} C_S$$

Initial conditions

$$C_{V,0} = \frac{\text{GPP}_0}{(k_{\text{AR}} + k_{\text{LF}})}$$

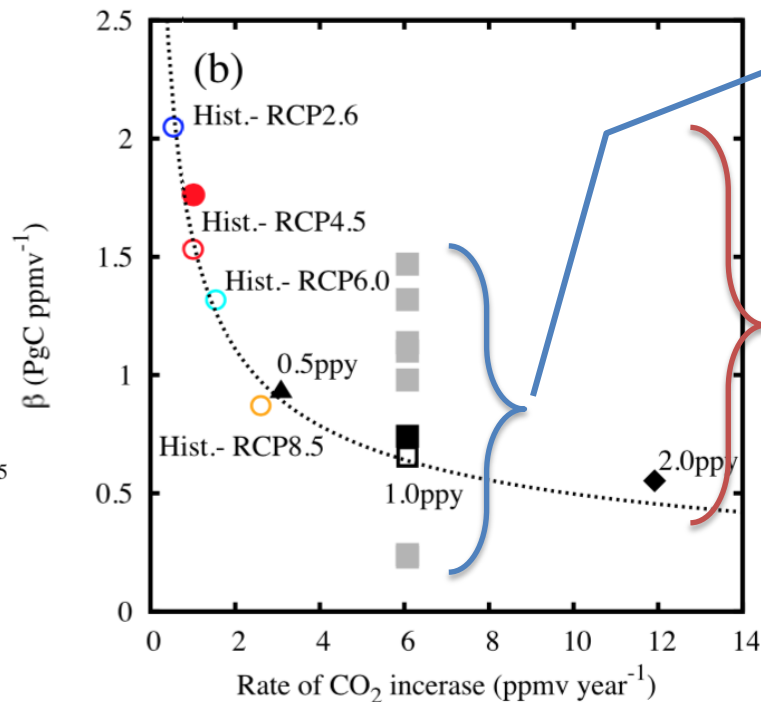

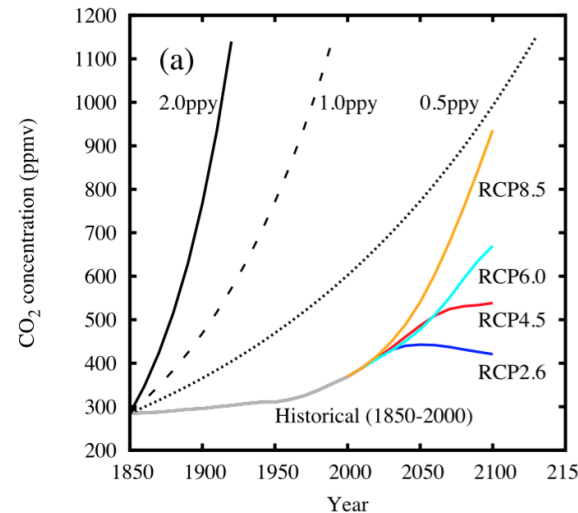

$$C_{S,0} = \frac{k_{\text{LF}}}{k_{\text{HR}}} \frac{\text{GPP}_0}{(k_{\text{AR}} + k_{\text{LF}})}$$

# Carbon storage change in different scenarios

- At the carbon state in a same level of CO<sub>2</sub> concentration, simulation with slower CO<sub>2</sub> increase scenario locates nearby the new equilibrium state.
- Beta, the concentration-carbon feedback parameter, is also affected by that.

# Other important issues: delayed response of carbon pools

Spread of:

- Single scenario
- Multi-model ensembles

Spread of:

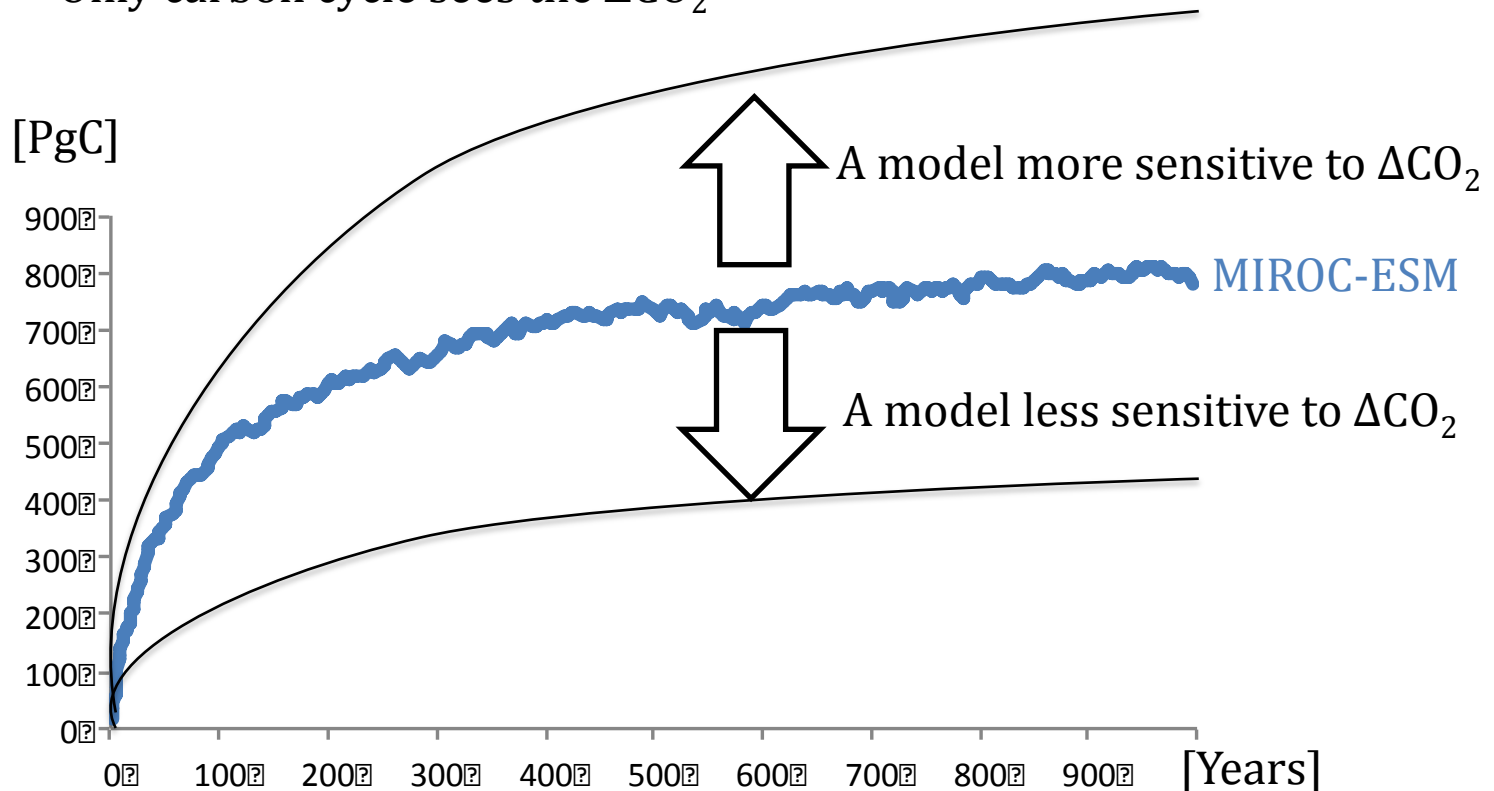

- Single model
- Multi-scenario simulations

Open marks: simplified model; closed: ESMs

- Terrestrial carbon changes induced by CO<sub>2</sub> fertilization effect strongly dependent on CO<sub>2</sub> scenarios
- This is because carbon pools have time-lag for the CO<sub>2</sub> forcing, which create different carbon states among different scenarios, even in a same CO<sub>2</sub> concentration.

# Equilibrium carbon state in doubled CO<sub>2</sub> concentration

- CO<sub>2</sub> conc. is abruptly doubled from P.I. state and fixed during 1000 years
- Only carbon cycle sees the  $\Delta\text{CO}_2$

- Transient simulations inevitably include the influence of 1) changes in CO<sub>2</sub> forcing and 2) the lags of carbon pools behind the forcing change.
- To assess the models' sensitivity to  $\Delta\text{CO}_2$  accurately, an experiment with abrupt CO<sub>2</sub> doubling/quadrupling might be better, because by using that we can remove the effect of the changing forcing.
- It may be meaningful to define equilibrium land carbon increase for 2xCO<sub>2</sub>.

# Summary

- We attempted to decompose the concentration–carbon feedback in the terrestrial carbon cycle into contributions by land ecosystem processes using outcomes of CMIP5 ESMs simulations.
- The large spread of  $\Delta C_L$  was well explained by the degree of NPP response to  $\Delta CO_2$  increase in each model, but models increase their NPP by different manner.
- In order to constrain the response to  $CO_2$  increase, the decomposition used in this study and comparing the each term with observation data will be useful.
- There is a strong scenario dependence in the magnitude of  $CO_2$  fertilization for a certain concentration level . Using a stabilized concentration scenario makes the analysis simpler.
- Similar to equilibrium climate sensitivity, it may be useful to define the equilibrium land carbon increase for the  $2xCO_2$  level.
